Lipids were analyzed in thirteen species of brown algae collected at the seashore near Tokyo, Japan. Diacylglycerylhydroxymethyltrimethyl- β -alanine (DGTA), a recently identified betaine lipid, was found as a major lipid component in eight species of brown algae examined, namely, *Ishige okamurai*, *Dictyota dichotoma*, *Pachydictyon coriaceum*, *Padina arborescens*, *Hizikia fusiformis*, *Sargassum horneri*, *S. ringgoldianum* and *S. thunbergii*. However, phosphatidylcholine (PC) was not detected in any of these algae except *I. okamurai*. By contrast, PC was found as a major lipid component in five other species, namely, *Colpomenia sinuosa*, *Endarachne binghamiae*, *Scytosiphon lomentarius*, *Eisenia bicyclis*, *Undaria pinnatifida*. These algae in turn did not contain detectable amounts of DGTA. The fatty acid composition of four selected species, *S. lomentarius*, *U. pinnatifida*, *D. dichotoma* and *H. fusiformis*, was also studied. The fatty acid components of DGTA in *D. dichotoma* and *H. fusiformis* were similar to those of PC in *U. pinnatifida*, the major components being 16:0, 18:2 and 20:4 ω 6 (also 16:1 in *D. dichotoma*).

Key words: Betaine lipid — Brown algae — DGTA — Fatty acid — Phosphatidylcholine.

Brown algae (Phaeophyceae) are an important group in the Chromophyta. They contain Chls *a* and *c* as photosynthetic pigments and are yellowish-brown in color (Green et al. 1989). In spite of the fact that some species of brown algae, such as *Undaria pinnatifida*, *Hizikia fusiformis* and *Laminaria japonica*, are important sources of food in Japan, there are few reports on the lipids of the brown algae. Different sulfur-containing lipids from three species of Fucaceae were described by Pham Quang Liem and Laur (1976a, b). Smith and Harwood (1984) analyzed the lipids from *Fucus serratus*, and they reported an

unknown Dragendorff-positive lipid which was clearly distinguishable by TLC from PC and DGTS. The same compound was also present in *Ascophyllum nodosum* (Jones and Harwood 1987). In the course of studies on the lipid composition of three species of brown algae, namely, *Hizikia fusiformis*, *Undaria pinnatifida* and *Scytosiphon lomentarius*, we found that *H. fusiformis* contained an unidentified, Dragendorff-positive lipid which was similar to the unknown lipid detected by Smith and Harwood (1984), while the lipid was not present in *U. pinnatifida* and *S. lomentarius* (Araki et al. 1989). *H. fusiformis* contained PC at a level that corresponded to less than 1% of the total lipids, whereas this lipid was a major component (more than 10% of the total) in *U. pinnatifida* and *S. lomentarius*.

The unknown lipid from *H. fusiformis* appeared to be very similar to DGTA which was isolated originally from *Ochromonas danica* (Vogel et al. 1990). DGTS, another betaine lipid from *O. danica*, was isolated by Brown and Elovson (1974). DGTS has been found in many species of green algae (Eichenberger 1982, Sato and Furuya 1985), as well as in pteridophytes and bryophytes (Sato and Furuya

Abbreviations: MGDG, monogalactosyl diacylglycerol; DGDG, digalactosyl diacylglycerol; SQDG, sulfoquinovosyl diacylglycerol; PC, phosphatidylcholine; PE, phosphatidylethanolamine; PG, phosphatidylglycerol; PI, phosphatidylinositol; PS, phosphatidylserine; DGTS, 1(3),2-diacylglyceryl-3(1)-*O*-4'-(*N,N,N*-trimethyl)homoserine; DGTA, 1(3),2-diacylglyceryl-3(1)-*O*-2'-(hydroxymethyl)(*N,N,N*-trimethyl)- β -alanine; TLC, thin-layer chromatography.

1984a, b). Since DGTA turned out to be identical to the Dragendorff-positive lipid from *Fucus* and *Ascophyllum* (Vogel et al. 1990), it seemed very likely that it would also be present in *H. fusiformis* and other brown algae.

In the present report we describe the identification of DGTA and the distribution of DGTA and PC among different species of brown algae.

Materials and Methods

Plant materials—Fronds of thirteen species of brown algae, namely, *Colpomenia sinuosa*, *Dictyota dichotoma*, *Eisenia bicyclis*, *Endarachne binghamiae*, *Hizikia fusiformis*, *Ishige okamurai*, *Pachydictyon coriaceum*, *Padina arborescens*, *Sargassum horneri*, *S. thunbergii*, *S. ringgoldianum*, *Scytosiphon lomentarius* and *Undaria pinnatifida*, were collected at Hayama, on the west coast of the Miura Peninsula, near Tokyo, on March 26, 1990.

Male gametophytes of *Ectocarpus siliculosus*, *Laminaria digitata* and thalli of *Sargassum muticum* were obtained from the algal collection at the University of Konstanz, F.R.G. (Prof. D. G. Müller). These algae were used for qualitative analyses only.

Extraction and separation of lipids—Fronds were washed with distilled water, blotted on filter paper, weighed and cut into small pieces. Lipids were extracted from fresh or lyophilized materials with a mixture of chloroform/methanol (1:1, v/v) according to the method of Bligh and Dyer (1959), and then lipid were fractionated into individual lipid classes by two-dimensional TLC on precoated silica-gel plates (20 cm × 20 cm, Merck 5721 and 5715; Merck) using, as solvents for development, a mixture of acetone/benzene/methanol/water (8:3:2:1, v/v, solvent 1) in the first dimension and a mixture of chloroform/acetone/methanol/acetic acid/water (10:4:2:3:1, v/v, solvent 2) in the second dimension (Sato and Furuya 1984a). As an alternative solvent system, a mixture of chloroform/methanol/water (65:25:4, v/v, solvent 3) in the first dimension and a mixture of chloroform/methanol/isopropylamine/conc NH₃ (65:35:0.5:5, v/v, solvent 4) in the second dimension were used (Eichenberger 1982). The lipids from *O. danica* (a chrysophyte) and *Porphyra yezoensis* (a red alga) were used as references. For semi-preparative work, lipids were separated by TLC in solvent 3. The Dragendorff-positive lipid was eluted from the plates with a mixture of chloroform/methanol (2:1, v/v) and purified either by TLC in solvent 4 or by HPLC on a Perkin-Elmer Series 10 Liquid Chromatograph equipped with a column (4 mm × 250 mm) of Nucleosil 100 10 µm (Knauer, Hamburg, F.R.G.). The solvent was a gradient of acetonitrile that contained 2.5–15% water during elution for 10 min, 15–20% water for 5 min and 20% water for 5 min. The flow rate was 1.5 ml min⁻¹ and peaks were detected with a Perkin-Elmer LC-75

detector at 210 nm. DGTA had a retention time of 14.3 min. IR spectra were measured on a KBr support in a Perkin-Elmer 782 spectrophotometer.

Analysis of fatty acid composition—Lipids were visualized on TLC plates by spraying with a fluorescent dye, primuline, dissolved in 80% aqueous acetone. Spots were scraped off and treated with 5% hydrogen chloride in methanol at 90°C for 2 h. The resulting fatty acid methyl esters were analyzed in a gas-liquid chromatograph (GC-9A, Shimadzu, Japan) as described earlier (Araki et al. 1986). The amount of each lipid was determined from the amounts of its constituent fatty acids.

Results

Detection of DGTA from brown algae—Figures 1A and 1B show typical patterns of separation by TLC of total lipids from *Hizikia fusiformis* (A) and *Undaria pinnatifida* (B). Spot 7 in Fig. 1A reacted positively to Dragendorff reagent and was neither a phospholipid nor DGTS, as judged from the R_f value in the two-dimensional TLC. This lipid was not found in *U. pinnatifida* (Fig. 1B). The two-dimensional TLC using solvents 3 and 4 showed that *D. dichotoma*, *H. fusiformis*, *I. okamurai*, *P. arborescens*, *S. horneri*, *S. muticum* and *S. ringgoldianum* contained a lipid that migrated to the same position as authentic DGTA from *O. danica* (not shown).

IR spectra of the lipid from six species of brown algae are shown in Fig. 2. Absorption bands due to C=O (1,740 cm⁻¹), COO⁻ (1,605 cm⁻¹), C—O—C ester (1,175 cm⁻¹), C—O—C ether (1,120 cm⁻¹) and N⁺ (CH₃)₃ (970 cm⁻¹) were characteristic of all the spectra and were completely consistent with those of authentic DGTA from *Ochromonas danica* (Vogel et al. 1990) and *Fucus vesiculosus* (not shown). From these findings, we identified the lipid in spot 7 as DGTA.

Lipid composition of brown algae—The composition of the lipids in thirteen species of brown algae is presented in Table 1. DGTA was detected in eight species, namely, *D. dichotoma*, *H. fusiformis*, *I. okamurai*, *P. arborescens*, *P. coriaceum*, *S. horneri*, *S. thunbergii* and *S. ringgoldianum*. It is noteworthy that no PC was found in these species of algae, with the exception of *I. okamurai* and *S. thunbergii* which contained small amount of PC. In addition, PE was not found in *P. coriaceum* and *D. dichotoma*. By contrast, large amounts of PC were detected in *C. sinuosa*, *E. binghamie*, *E. bicyclis*, *S. lomentarius* and *U. pinnatifida*, whereas DGTA was not found in these species of algae. *I. okamurai* was the only brown alga analyzed that contained DGTA as well as PC and PE in considerable amounts. From the data obtained by TLC, *S. muticum* appeared to be another species of *Sargassum* that contained DGTA but not PC, and DGTA was absent from *E. siliculosus* and *L. digitata*. However,

Fig. 1 Thin-layer chromatograms of total lipids extracted from two different species of brown algae. A, *Hizikia fusiformis*; B, *Undaria pinnatifida*. 1, MGDG; 2, DGDG; 3, SQDG; 4, PG; 5, PE; 6, unknown (probably PA); 7, DGTA; 8, PC; 9, PS; 10, PI. Solvents: 1st dimension, acetone/benzene/methanol/water (8 : 3 : 2 : 1, by vol); 2nd dimension, chloroform/acetone/methanol/acetic acid/water (10 : 4 : 2 : 3 : 1 by vol).

both these latter species contained PC and PE (data not shown).

MGDG, DGDG, SQDG and PC (or DGTA) were the

major components of the lipids from most of the species of brown algae examined, while PG, PE, PI, PS were minor components. However, *E. bicyclis* and *U. pinnatifida* contained PG and PE at a higher level that corresponded to about 10% of the total.

Fatty acid composition of brown algae—The composition of fatty acids was analyzed in two species of brown algae that contained DGTA, namely, *H. fusiformis* and *D. dichotoma* (Table 2) and in two other species that lacked DGTA, namely, *U. pinnatifida* and *S. lomentarius* (Table 3).

In *H. fusiformis* and *D. dichotoma*, the major components of fatty acids in DGTA were 16:0 and 20:4 ω 6 (also 16:1 in *D. dichotoma*). This composition is quite different from the fatty acid composition of DGTA from *Ochromonas* (Vogel et al. 1990), in which 18:0, 20:4 and 22:5 were the major acids. In PC of *S. lomentarius* and *U. pinnatifida*, the major fatty acids were 16:0, 20:4 ω 6 and 20:5 ω 3. The fatty acid composition of PE was rather similar to those of PC and DGTA, but the level of 16:0 in PE was lower than that in PC or DGTA.

18:4 and 20:5 ω 3 were the major fatty acid components of MGDG and DGDG from each of the four species of brown algae analyzed, although some differences in the levels of individual fatty acids were noted. 16:0, 18:1 and 18:3 ω 3 were the major components of SQDG, while 16:0, 16:1 t , 18:1 and 18:3 ω 3 were abundant in PG. It was also noted that *D. dichotoma* contained a significant amount of 16:1 in most of the lipid classes.

Discussion

Occurrence of DGTA in brown algae—DGTA, a recently discovered betaine lipid, was detected in the nine species of brown algae analyzed in the present study.

Based on these results, a clear relationship is apparent between the distribution of DGTA and the systematics of brown algae. *P. coriaceum*, *D. dichotoma* and *P. arborescens* belong to the order Dictyotales while *H. fusiformis*, *S. horneri*, *S. muticum*, *S. ringgoldianum* and

S. thunbergii are included in the order Fucales. In *Fucus vesiculosus*, *F. serratus* and *A. nodosum*, all of which are members of the same order, the presence of DGTA has already been demonstrated (Jones and Harwood 1987, Vogel et al. 1990). *Ishige okamurai*, the only representative species analyzed from the order Chordariales, also contains DGTA. Thus, it appears, so far, that the distribution of DGTA among brown algae is limited to certain orders, examples of which are the orders, Dictyotales, Fucales and Chordariales. In contrast, members of the order Ectocarpales, Scytosiphonales and Laminariales do not contain DGTA. Obviously, more work is necessary to establish the phylogenetic distribution of DGTA among the brown algae, which comprise 15 different orders (Henry 1984, Wynne 1982). It should be emphasized that DGTS, the other known betaine lipid, which is typical of many green algae, pteridophytes and bryophytes, has not been found in brown algae so far.

In seven of nine species of brown algae, PC seems to be replaced by DGTA. This situation contrasts clearly with the lipid composition of many green algae, in which PC is largely replaced by DGTS, another betaine lipid (Eichenberger 1982, Sato and Furuya 1985). It is still premature to make generalizations about the distribution of DGTA in Chromophyta, the group of algae that contain Chls. *a* and *c*. *O. danica* is the organism in which DGTA was discovered (Vogel et al. 1990). A raphidophyte, *Chattonella antiqua* (Sato et al. 1988) contained DGTS but no DGTA, whereas a marine diatom, *Phaeodactylum tricornutum* (Arao et al. 1987) contained neither DGTS nor DGTA.

Fatty acid composition of individual lipid classes—The fatty acid patterns of DGTA in *D. dichotoma* and

H. fusiformis were similar to that of PC in *U. pinnatifida*. The major components were 16:0, 18:2 and 20:4 ω 6 (also 16:1 in *D. dichotoma*).

The fatty acid composition of individual lipid classes of these species of brown algae, except for *D. dichotoma*, were essentially similar to that of *F. serratus* (Smith and Harwood 1984), although the contents of C20 polyunsaturated acids in SQDG and PG were somewhat higher in *F. serratus*. The major fatty acids in glycolipids (MGDG and DGDG) are mainly C18 and C20 polyunsaturated fatty acids, whereas the phospholipids (PC, PE) and DGTA mainly contained polyunsaturated C20 fatty acids. Such was the case in *F. serratus* (Smith and Harwood 1984) and in the raphidophycean alga, *C. antiqua* (Sato et al. 1988). The fatty acid pattern of a marine diatom, *P. tricornutum* (Arao et al. 1987) was, however, quite different in that it contained high levels of 20:5 ω 3 in all the lipid classes.

Giroud and Eichenberger (1989) reported that DGTS from *Chlamydomonas*, in which no PC was found, might be actively involved in the metabolism of lipids. This betaine lipid is suggested to act as a primary acceptor of exogenous fatty acids and as a substrate of fatty acid desaturases in *Chlamydomonas* (Giroud and Eichenberger 1989), as well as in *O. danica* and *Acetabularia* (Eichenberger, unpublished results). Although DGTS was not found in brown algae examined, the fact that DGTA was found primarily in the species that do not contain PC suggests that DGTA might play a specific role in the synthesis of lipids in brown algae. This assumption is strongly supported by the rapid labelling of DGTA on incubation of *F. serratus* and *A. nodosum* with [14 C]acetate (Smith and Harwood 1984, Jones and Harwood 1987).

The authors wish to thank Prof. D. G. Müller, University of Konstanz, F.R.G., for samples of *Ectocarpus*, *Laminaria* and *Sargassum*, and for helpful discussions. The work was supported by Grant 3.061-0.87 from the Swiss National Science Foundation.
